(Received January 23, 1985; revised September 1, 1986)

The effect of air pollution caused by automobile exhausts and industries were studied on the chlorophyll and protein contents of some plants growing in Karachi. In general, pollution stress showed a decrease in the chlorophyll and protein contents in all the species examined except for *Ficus benghalensis* which showed almost equal amount of chlorophyll in control and polluted plants. Possible explanations for these changes caused by environmental pollution are discussed.

Key words: Pollution, Protein, Plants.

INTRODUCTION

In industrialized cities transportation is the most important source of atmospheric pollution contributing about 60 per cent of the total. The main sources of pollution are carbon monoxide, hydrocarbon, oxides of sulphur and nitrogen and particulate matter. These pollutants react to form a photochemical smog which is more toxic than the original emission [1]. Industries are another major source of atmospheric pollution contributing to about 16% of the total [2]. In Karachi, the Sind Industrial Trading Estate (SITE) area is the central place where textile, soap, pharmaceutical and chemical industries are located. Industries emit the most diversified pollutants, sulphur oxides being its primary pollutant.

These toxic substances adversely affect man's food supply by affecting growing plants which are particularly susceptible to pollution. These pollutants before causing visible injury to plants cause invisible injury which is due to changes in the normal metabolism of plants.

Almost no work has been carried out on the effect of phytotoxic air pollutants on plant metabolism in Pakistan. Zahoor and Qadir [3] made some studies on the changes in chlorophyll and carbohydrate contents and Ismail and Ahmed [4] studied the effect of phytotoxic air pollutants on changes in the amino acid content.

The present investigation deals with the effect of phytotoxic air pollutants on the protein and chlorophyll contents of some roadside and industrial area plants of the Karachi region.

MATERIALS AND METHODS

Fully mature and healthy leaf samples from about 3 meter height of the plant were collected in late morning during the middle of December 1982.

Leaf samples of *Nerium oleander* L., *Eucalyptus* spp, *Ficus benghalensis* L., *F. religiosa*, L., *Alstonia scholaris*, R.Br., *Samanea saman* (Jacq.) Merrill, *Guaiacum officinale* L., *Murraya exotica* L., were collected from Gurumandir whereas *Syzygium cumini* (L) Skeels, *Salsola baryosma* (R&S) Dandy., *F. benghalensis* L., *N. oleander* L. and *Thespesia populnea* (L) Soland ex Correa were collected from SITE and *Calotropis procera* (Willd.) R.Br., was collected from the vicinity of the National Cement Factory. For comparative studies, leaves of the same species and of approximately same physiological age were collected from the Karachi University Campus where the atmosphere is relatively less polluted. Plant samples of University Campus were used as control against the test samples.

Protein contents were determined by Lowry's method and the chlorophyll contents were determined by Maclachlan and Zaliks [6] method.

RESULTS

The chlorophyll content of roadside and industrial area plants. All plants growing along roadside and in the industrial area showed a decrease in chlorophyll content except for *F. benghalensis* which showed almost an equal amount of chlorophyll in control and polluted plants (Table 1). Among roadside plants *Ficus benghalensis*

DISCUSSION

Decrease in the chlorophyll and protein contents in roadside plants may be attributed to the air pollutant derived from automobile exhausts. These pollutants react to form a photochemical smog which appears to be more toxic than the original emission.

The SITE area is the central place where textile, soap, pharmaceutical and chemical industries are located. These industries cause air, water and soil pollution. Industrial wastes contain toxic organic solvents, cadmium, nickel, zinc, lead etc. The cement factory located in Gulshan-e-

Iqbal discharges carbon monoxide, carbon dioxide, dust particles, sulphur and lime particles [7]. Changes in the chlorophyll and protein content of industrial area plant may be due to these pollutants causing air, soil and water pollution.

Reduction in chlorophyll content was observed by many workers [3, 8, 9, 10, 11]. Pollutants may affect chlorophyll molecules directly or impair synthesis of new chlorophyll by affecting the chlorophyll structure. Sometimes a pollutant affects the chloroplastic membrane and changes the shape of the chloroplast or destroys it. William *et al.* [12] observed that changes occur in stroma of chloroplasts and involve either a granulation of the stroma or the formation of fibrils or plates. Sakaki [13] observed that the breakdown of photosynthetic pigments started only after the disintegration of thylakoid membranes.

The present investigation showed that the concentration of proteins decrease in polluted plants. Decrease in protein content due to the pollutant was confirmed by many workers [10, 14, 15]. Decrease in protein could be attributed to enhanced protein degradation or the inhibition of protein synthesis without affecting amino acid synthesis. The latter would tend to increase the concentration of free amino acids. This conclusion is supported by our previous work [4]. Protein synthesis is related to RNA, and any change in RNA will affect the protein level. Many workers observed decrease in RNA and protein levels in polluted plants [9, 16].

The rate of clotting of milk was affected by the concentration of carbon source. The rate of clotting of milk was affected by the concentration of carbon source.

RESULTS AND DISCUSSION

Tables 1, 2 and 3 show the results of the present study. Effect of time pH and temperature on the milk clotting activity of *A. oryzae* was studied by using glucose and fructose as the carbon source. Effect of incubation time, pH and temperature on milk clotting activity was studied. It was noted that the rate of clotting activity was affected by the concentration of carbon source.

MATERIALS AND METHODS

Aspergillus oryzae was used for the study. Stock culture was maintained on Dextrose Agar medium. (A) Preparation of enzyme extract: A simple medium of the following composition was used.

Peptone, 20 g; K₂HPO₄, 30 g; KH₂PO₄, 10 g; NaCl, 10 g; KCl, 30 g; MgSO₄·7H₂O, 10 g; and glucose, 10 g/lit

Glucose was also substituted by fructose. The pH of the medium was adjusted to 5.6 before inoculation. The medium was distributed in conical flasks and sterilized for 15 min at 15 lb pressure. After inoculating the sterilized media, the flasks were placed on a rotary shaker with 150 rpm at 30° for three days. Following (50 ml) was used in each flask as a preservative and the enzyme was extracted with tap water for twenty hours at room temperature. On filtration, the filtrate was used for the enzyme assay.

Table 1. Effect of incubation time and carbon source on the milk clotting activity

Incubation time	24	48	72	96	120
Time of clotting					
With glucose (hr)	3	2	4-40	4	2-10
With fructose (hr)	4-30	4-30	4-00	3-30	4-30
