# Electronic Spectral Properties of Substituted Azouracil Compounds 

Mamdouh S Masoud ${ }^{*}$, Ahmed M Hindawy and Rabah H Ahmed<br>Chemistry Department, Faculty of Science, Alexandria University, Alexandria, Egypt

(Received 14 October 1997; accepted 31 March 1998)

#### Abstract

Synthesis of 5-(substituted phenylazo) uracil compounds (I) have been reported. The analytical data and ${ }^{1} \mathrm{H}-\mathrm{NMR}$ are used to elucidate the structures. The electronic spectral properties of the organic compounds were investigated in presence of different solvents and at different pH 's. The pK 's values were determined and related with the molecular structure of the compounds. The electronic transitions were assigned. The phenomenon of tautomerism was explained. The shifts in peak locations in the electronic spectra of the organic compounds have been correlated with different solvent polarity parameters.

$\mathrm{X}=-\mathrm{H} ; 2-\mathrm{CH}_{3} ; 3 \mathrm{CH}_{3} ; 3-\mathrm{OH} ; 2-\mathrm{COOH} ; 4-\mathrm{COOH} ; 2-\mathrm{Cl} ; 3-\mathrm{Cl} ; 4-\mathrm{Cl} ; 2-\mathrm{Br}$; $3-\mathrm{NO}_{2} ; 2,5-\mathrm{diCH}_{3} ; 2,5-\mathrm{diCl}$ and $2,4-\mathrm{diCl}$.

## Introduction

Azo compounds are by far the most important class of dyes comprising over $50 \%$ of total world dye stuffs production (Patai 1975). The formation of metal complexes has figured prominently in dye stuff chemistry from very early times. The azo group is connected with a number of important biological reactions such as protein synthesis (Tu et al 1974), inhibition of carcinogenesis (Rosenberg 1971), immuno chemical affinity and nitrogen fixation (Eichhorn 1973). The pyrimidine compounds are important class of compounds for their structural chemistry and biological activities.

In our laboratory (Vogel 1961; Masoud et al 1991; Masoud et al 1992 a,b,c; Khalil et al 1993; Masoud et al 1994 a,b,c), a series of papers have been published about the structural chemistry of the pyrimidine compounds especially those containing azo group.

In the present paper, the electronic spectra of 5-(substituted phenylazo) uracil compounds in different organic solvents and at different pH 's have been analyzed. The major objective of such work lies in the following:
(i) Evaluation of the pK 's values and their interpreting them in relation to the molecular structure of the compounds, (ii) the assignment of the electronic transition, (iii) explaining the phenomena of tautomerism, (iv) illustrating the type of hydrogen bonding, (v) the shift in the peak position is correlated to

[^0]different solvent polarity parameters using the multiple linear regression technique.

## Experimental

The 5-(Substituted phenylazo) uracil compounds containing groups with different electronic properties ( $-\mathrm{H}, 2-\mathrm{CH}_{3} ; 3-\mathrm{CH}_{3}$; 3-OH; 2-COOH; 4-COOH; 2-Cl; 3-Cl; 4-Cl; 2-Br; 3-No 2 ; 2,5$\mathrm{diCH}_{3} ; 2,5-\mathrm{diCl}$ and $2,4-\mathrm{diCl}$ ) were prepared by usual method of diazotization of phenolic compounds (Vogel 1961). The compounds (I) were characterized by their elemental analysis given in Table 1.
${ }^{1} \mathrm{H}$-NMR of the organic compounds in presence of $\mathrm{d}^{6}$-DMSO or d ${ }^{1}-\mathrm{HCCl}_{3}$ were recorded on Varain EM-Model 3930-90 MHz Spectrometer. Tetramethylsilane (TMS) was used as an internal standard.

The electronic spectra were recorded using Pye Unicam SP 1800 Spectrophotometer at different pH's (1.03-10.80) and in the presence of different solvents.

Universal buffer solutions were prepared as usual. Dioxane and ethanol solvents were purchased from BDH and Merck companies and were purified following published methods. The other solvents, (cyclohexane, chloroform, carbontetrachloride. DMF, DMSO, acetonitrile, acetone, aq. $\mathrm{NH}_{3}$ and ether) were of spectroquality grade.

Method of Calculations. The observed peak location of an absorption band Y in a given solvent has been expressed as a
linear function of different solvent polarity parameters $x_{1}, x_{2}$, $\mathrm{X}_{3}, \ldots, \mathrm{x}_{\mathrm{n}}$ as follows:

$$
Y=a_{0}+a_{1} x_{1}+a_{2} x_{2}+a_{3} x_{3}+\ldots+a_{n} x_{n} \ldots \ldots . \text { (i) }
$$

This equation is amendable to solution for the intercept $a_{0}$ an the coefficients $a_{1}, a_{2}, \ldots ., a_{n}$ by multiple regression. The multiple regression (R) or (MCC) and the probability of variation ( P ), which are calculated from the modified SPSS programme, have been considered as a measure of the goodness of the fit. The regression intercept $a_{0}$ has been considered as the peak position in the gas phase spectra. Several one, two three and four-parameters equations have been used to correlate the spectral shifts with various empirical solvent polarity parameters which are

$$
\begin{align*}
& \mathrm{E}=2.859 \times 10^{-3} v \ldots \ldots \ldots . . \text { (ii) } \\
& K=(D-1) /(2 D+1) \ldots \ldots \ldots . . \text { (iii) } \\
& M=\left(n^{2}-1\right) /\left(2 n^{2}+1\right) \ldots \ldots . \text { (iv) } \\
& \mathrm{J}=(\mathrm{D}-1 /(\mathrm{D}+2) \text {. }  \tag{v}\\
& \mathrm{H}=\left(\mathrm{n}^{2}-1\right) /\left(\mathrm{n}^{2}+2\right) \ldots \ldots \ldots \ldots . \text { (vi) } \\
& \mathrm{N}=\mathrm{J}-\mathrm{H} \text {. } \tag{vii}
\end{align*}
$$

The parameter E given by equation (ii) is related to $v$ which is the wave number of the absorption maximum (Masoud et al 1993). This function is sensitive to both solvent-solute hydrogen bonding and dipolar interactions. The dielectric function K adequately represents the dipolar interactions and is related to the dielectric constant (D) of the solvent (Masoud et al 1993). The functions J and H have been introduced to account for the non-specific solute-solvent interactions such as dispersion and dipolar effects (Masoud et al 1993). These are related to the dielectric constant and refractive index ( $n$ ) of the solvents, respectively. The functions M and N have been introduced to account for the solute permanent dipole-solvent induced dipole and solute permanent dipole-solvent permanent dipole interactions, respectively (Hillard et al 1981).

## Results and Discussion

a) NMR Spectroscopy. The ${ }^{1} \mathrm{H}$ NMR spectra of uracil and its 5-substituted arylazo compounds are present in Table 2.

1) The multiple signals in the range 6.9-8.0 ppm are assigned for phenyl protons with total number of 4 protons except the phenylazouracil and 2, 4-dichloro compounds where the number of protons is 5 and 3, respectively. (2) A doublet signal at $5.3-5.5 \mathrm{ppm}$ is due to 2 CH for uracil and 1 CH for its phenylazo derivatives. (3) A sharp doublet signal at 3.9-4.1 ppm is due to $-\mathrm{OCH}_{3}$ group. (4) The doublet broad signal at $6.7-6.9 \mathrm{ppm}$ is assigned for the protons of the - COOH group
attached to the phenyl ring. (5) The hydroxy group gave a broad signal at $8.6-8.9 \mathrm{ppm}$ for the 3 -hydroxy compound, probably in a dimeric structure. (6) The broad band at 10.4 11.1 ppm is due to NH group to assign the presence of the keto group. This band is absent in compounds containing- $\mathrm{H}, 2-$ $\mathrm{OCH}_{3}$, and $2-\mathrm{Cl}$ substituents, probably due to strong solute solvent interaction. (7) The presence of doublet signals at 7.47.6 ppm and $7.8-8.0 \mathrm{ppm}$ in $2-\mathrm{COOH}$ and $4-\mathrm{COOH}$ substituted arylazo compounds, respectively are related to the presence of intramolecular hydrogen bond. (8) The signals 7.7-7.9 and 8.7-8.9 ppm for the parent phenylazo and its $2-\mathrm{Cl}$ substitutent, respectively are due to NH ...O hydrogen bonded structure. (9) In general, the strength of the intramolecular hydrogen bond of the NH...O type is greatly influenced by the nature of the substituent. The electron withdrawing substituents decrease the intramolecular hydrogen bond to a great extent as indicated by the strong shift of the - OH signal. The electron donating substituents show the presence of intramolecular hydrogen bond of the NH...O due to the increasing basicity of the azo nitrogen.

The following possible structures are given:

$X=3-\mathrm{OH}, 2-, 4-\mathrm{COOH}, 2-\mathrm{OCH}_{3}\left(\right.$ in $\left.\mathrm{CDCl}_{3}\right) \& 2,4-$ diCl
(b) Electronic Spectroscopy. The effect of pH on the electronic absorption spectra of the organic compounds gave different $\lambda_{\max }$ with some isobestic points. For uracil, two characteristic bands at 208 and 258 nm are due to $\pi-\pi^{*}$ transition.

The second is vanished in solutions with $\mathrm{pH}>9$ with the existence of a new band at 285 nm , due to the existence of an intramolecular hydrogen bond between (N(3)H \& N(1)H) with $2 \mathrm{C}=\mathrm{O}$. The first band assigned to the increase of the aromatic character of uracil ring.

On comparing the electron absorption spectra of the azo compounds to that of uracil, more bands are observed. Two $\pi$ $\pi^{*}$ transition bands are observed at (234 up to 250) and (260 up to 286$) \mathrm{nm}$, due to the shift of the tautomeric equilibrium towards the enol form in moderately basic solutions. The band at 350 nm is due to $n-\pi^{*}$ transition of CT nature of the azo group as a donor site, while that at 430-450 nm is due to the existence of azo $\rightarrow$ hydrazo equilibrium.

Different positions are available for protonation - $\mathrm{NH}, \mathrm{C}=\mathrm{O}$ and $\mathrm{N}=\mathrm{N}$ to give ${ }^{+} \mathrm{NH}_{2}, \mathrm{C}=\mathrm{O}^{+} \mathrm{H}$ and $\mathrm{N}=\mathrm{N}^{+} \mathrm{H}$, respectively. The proton is bound symmetrically to both N atoms, i.e., acts as a single basic site or the proton is bound to the azo group in the form of $\pi=$ complex. The azo group can act as a proton acceptor in hydrogen bonds. The aromatic azo compounds are resonance stabilized and tautomerism involving the azo group is well known (Jaffe 1953). The new band recorded for $2-\mathrm{OCH}_{3}$ compound at 530 nm , is probably due to the existence of hydrazo structure. However, for the $3-\mathrm{OH}$ compound, the absence of 250 nm band argued the slight contribution of the enol tautomer beside the protonated species.

For the absorbance-pH relationships, the half-height (Issa 1971) and the modified limiting absorption (Muk and Pravica 1969) methods to evaluate the $\mathrm{pK}_{\mathrm{a}}$ values gave concordant results (Table 3). All the compounds gave one $\mathrm{pK}_{\mathrm{a}}$ in the range 6.9-9.7 due to the ionization of - OH group, except the $2-$ $\mathrm{OCH}_{3} ; 3-\mathrm{OH} ; 2-\mathrm{COOH} ; 2-\mathrm{Cl} ; 3-\mathrm{Cl} ; 4-\mathrm{Cl} ; 2-\mathrm{Br} ; 4-\mathrm{COOH} ; 2,5-$ $\mathrm{diCH}_{3}$ and $2,4-\mathrm{diCl}$ compounds which gave more than one $\mathrm{pK}_{\mathrm{a}}$, due to the ionization of the two - OH groups.
due to the ionization of the phenolic-OH group. However, the $\mathrm{pK}_{\mathrm{a}}$ of $4-\mathrm{COOH}$ and $2-\mathrm{COOH}$ compounds are 5.4 and 7.0 , respectively due to the ionization of the carboxy group (Masoud et al 1985). The unexpected high $\mathrm{pK}_{\mathrm{a}}$ (7.0) of ionization of COOH group suggests the formation of strong intramolecular H-bond, i e, the carboxy behaves as an electron donor since it ionized through its resonating structure (Masoud et al 1985). The $\mathrm{pK}_{2}$ values are in the order $4-\mathrm{Cl}>2-\mathrm{Cl}>3-\mathrm{Cl}$, and correlated to the position and the electronic character of the substituents. The lower $\mathrm{pK}_{\mathrm{a}}$ values of 2-and 3-Cl substituents compounds than that of uracil are due to the electron attracting property of chlorophenylazo group. The $\mathrm{pK}_{\mathrm{Br}}>\mathrm{pK}_{\mathrm{C}}$, is due to the high electronegativity of -Cl atom.

The higher $\mathrm{pK}_{\mathrm{a}}$ of $2,5-\mathrm{diCH}_{3}$ compound than that of $2-\mathrm{CH}_{3}$ compound, is due to the hyperconjugation and the basicity of the two $-\mathrm{CH}_{3}$ groups. The dichloro compounds are with higher $\mathrm{pK}_{\mathrm{a}}$ values due to the electron attracting property of the two Cl groups. The $\mathrm{pK}_{\mathrm{a}}$ of $2,5-\mathrm{diCl}$ is higher than that of $2,4-\mathrm{diCl}$. The mechanism of ionization of some compounds is given as follows:

The $\mathrm{pK}_{\mathrm{a}}$ of uracil is higher than that of phenylazouracil, due to the basicity of the azo group with the presence of different tautomeric structures. Also, the low $\mathrm{pK}_{\mathrm{a}}$ of $2-\mathrm{CH}_{3}$ is probably explained on the basis that the $-\mathrm{CH}_{3}$ group exists in a structure $-\mathrm{CH}_{2} \mathrm{H}^{+}$. The $\mathrm{pK}_{\mathrm{a}}$ of $2-\mathrm{OCH}_{3}$ is smaller than that of uracil but higher than that of $2-\mathrm{CH}_{3}$, probably due to the bulkiness of $\mathrm{OCH}_{3}$ group with the possible existence of different tautomeric forms. The $\mathrm{pK}_{\mathrm{a}}$ of $2-\mathrm{OCH}_{3}(5.6)$ is due to the ionization of the $-\mathrm{O}^{-} \mathrm{CH}_{2} \mathrm{H}^{+}$group. The value of $\mathrm{pK}_{\mathrm{a}}$ of $2-\mathrm{OCH}_{3}$ in nonbuffered media (9.4) is higher than that deduced in buffered media (8.2), probably due to the buffer, that may be form some molecular complexes. The $\mathrm{pK}_{\mathrm{a}}$ of $3-\mathrm{OH}$ compound (6.1) is

However, the electronic spectral data of the organic compounds are affected by the solvents of variable polarities (Table 5). The data showed that uracil gave $\pi-\pi *$ transition band at 254 nm which is red shifted with the decrease of the dielectric constant of the solvent. So, the solute molecule can act as the hydrogen donor in forming the hydrogen bond. This band is splitted in aq. $\mathrm{NH}_{3}$ and ether to $256,282 \& 260,286 \mathrm{~nm}$, respectively. (The band at 282-286 nm appeared in buffered media at $\mathrm{pH}>9$ ). Another $\pi-\pi^{*}$ transition band at 234 nm in ether has appeared and blue shifted with more polar hydrogen donor solvent, due to the presence of solute-solvent interaction through hydrogen bond formation. The new band at 330
and 334 nm in ether and acetone, respectively, has appeared with low intensity, due to the forbidden $n-\pi^{*}$ electronic transition of an electron from a lone pair orbital of N or O to the $\pi$-orbital of the ring system.

For phenylazouracil compound, a well defined band is appeared at 350 nm , due to the $\mathrm{n}-\pi^{*}$ electronic transition of CT nature with the azo group as a donor, i e , solute solvent interaction exists. The extra $n-\pi^{*}$ electronic transition in the wavelength range $286-294 \mathrm{~nm}$ is present in all solvents used, except in presence of acetone. On the other hand, the $\pi-\pi^{*}$ electronic transition at 234 nm is red shifted with the decrease of the dielectric constant of the solvent (similar to uracil), due to conjugation. The bands at 450 and 500 nm in $\mathrm{CCl}_{4}$ and
aq. $\mathrm{NH}_{3}$, respectively, are probably assigned the hydrazo structure (Basu Baul et al 1983).

The spectra of 2- $\mathrm{CH}_{3}$ compound is strongly similar to that of $3-\mathrm{CH}_{3}$ and $2-\mathrm{OCH}_{3}$ compounds. Three $\pi-\pi^{*}$ electronic transitions are detected at 288-300, 230-246 and 210-220 nm, and are assigned to the transition of the phenyl ring overlapped by a composite broad $\pi-\pi^{*}$ of the azo structure (Masoud and Khalil 1991). The spectra gave a characteristic $n-\pi^{*}$ transition band at 350 nm which is red shifted in presence of $\mathrm{CCl}_{4}$, $\mathrm{CHCl}_{3}, \mathrm{DMF}, \mathrm{DMSO}$ and aq. $\mathrm{NH}_{3}$ solvents. This points to solute-solvent interaction (Masoud and Haggag 1982), especially in aq. $\mathrm{NH}_{3}$ where the red shift is high. The band at 430470 nm is appeared in all solvents used except DMF, probably

due to hydrazo formation. Beside such finding, there is a band at $530-534 \mathrm{~nm}$ in $2-\mathrm{OCH}_{3}$ compound, probably due to the difference in the basicity between $-\mathrm{CH}_{3}$ and $-\mathrm{OCH}_{3}$ groups.

In $3-\mathrm{OH}$ compound, $\mathrm{n}-\pi^{*}$ electronic transition is assigned in the range $358-372 \mathrm{~nm}$ in ethanol, acetone and aq. $\mathrm{NH}_{3}$

|  | 10.5-11.2 (doublet broad) | NH |

solvents of a broad nature. It is absent in the other solvents. Since the -OH group is of a strong donor property, this band is assigned to be of intramolecular charge transfer behaviour. The band is red shifted in more polar solvents, due to more stabilization of excited state than ground state (Hasanein et al 1988). The disappearance of the $n-\pi^{*}$ transition for the azo group in $2-\mathrm{COOH}$ compound is probably due to the intramolecular hydrogen bond mainly between the carboxy and the azo groups (Alexander and Sleet 1970; Masoud and Khalil 1991; Masoud et al 1995), beside the steric effect of the 2-carboxy group. The $\pi-\pi^{*}$ transition at 206-230 nm in presence of hydrogen bonding solvents (e.g. ethanol, aq. $\mathrm{NH}_{3}$ and ether) is due to the presence of an external hydrogen bond affected through $K$ band (Dearden and Forbes 1960). In $4-\mathrm{COOH}$ compound, the $n-\pi^{*}$ transition of the azo group, is detected with no hydrogen bond between the -COOH and $-\mathrm{N}=\mathrm{N}$-groups. The $\pi$ $\pi^{*}$ electronic transition bands of the $2-\mathrm{COOH}$ compound are of great similarity to that of the $4-\mathrm{COOH}$ compound.

In case of $2-\mathrm{Cl}$ compound, the $\mathrm{n}-\pi^{*}$ of the azo group is appeared at longer wavelength than that of 5-(phenylazo) compound,

due to the electron attracting property of the choro group. In a similar scope of investigation, no dramatic changes are observed between the electronic absorption spectra of the $2-\mathrm{Cl}$ and both $3-\mathrm{Cl}$ and $4-\mathrm{Cl}$ derivatives. However, the $\lambda_{\text {max. }}$ of the $2-\mathrm{Cl}$ compound is at a lower position compared to both 3 - and 4-Cl compounds. Also, the electronic spectral features of the 2-bromo compound are of great similarity to the $3-\mathrm{Cl}$ compound. For the nitro compound, with the strong attracting property of the nitro group, the 3-nitro compound absorbs at a lower position than the chloro compounds.

In general, the arylazo group is sufficiently polar for proximity effects to become significant in the orthoposition. The tautomeric equilibrium controlled by the intensity of the spectral bands, is high in presence of basic solvents than in a alcohol. The electronic effect of the aryl group is transmitted through the azo group and the phenyl ring.

In $2,4-$ and $2,5-\mathrm{diCl}$ compounds, more chlorine leads to red shift of the electronic spectral bands with increasing the dielectric constant of the solvents (D). The $n-\pi^{*}$ band of the 2,4-diCl compound absorbs at a slightly lower $\lambda_{\text {max. }}$ than that of the $2,5-\mathrm{diCl}$ compound. The hydrazone species at $410-520$ nm is detected in presence of cyclohexane, DMF, DMSO, aq. $\mathrm{NH}_{3}$, acetone and $\mathrm{CCl}_{4}$ solvents and located at a higher $\lambda_{\text {max }}$. than the $2-\mathrm{Cl}$ compound, due to the presence of more electron attracting property of the two chloro groups. However, the $2,5-\mathrm{di}-\mathrm{CH}_{3}$ compound absorbs at a longer $\lambda_{\max }$, than either 2 or 3-tolyl, $2,5-\mathrm{diCl}$ and $2,4-\mathrm{diCl}$ compounds, dueo the hyper-
conjugation effect of the two $-\mathrm{CH}_{3}$ groups.
(c) Computer Analysis. The results of calculations for the organic compounds under investigation are collected in Tables $(4,6-9)$. For the uracil and its phenylazo compounds, the solvent spectral gregions are
$\left(Y_{1}=232-268, Y_{2}=270-308, Y_{3}=322-390 \& Y_{4}=430-458 \mathrm{~nm}\right)$.
Based on one parameter equation, the followings are observed:
(1) For $Y_{1}$ and $Y_{3}$, the best correlation for the compounds, among these single solvent polarity parameters has been obtained with M. So, the solute permanent dipole solvent induced dipole interaction is the most effective on the spectral shifts from the one parameter equation view. (2) Based on $Y_{2}$, the four parameters are poorly effective. But N \& K are more effective than M \& E . (3) Inspite of $\mathrm{E}, \mathrm{N}$ \& K are the most effective parameters based on $Y_{4}$ (due to hydrazo $\rightarrow$ azo) spectral analysis, the parameter $E$ is the power. This indicated that, the spectral shifts of visible band $Y_{4}$ are highly sensitive to solute-solvent H -bonding and the (D).

For two-parameters equations, we showed that: (1) The spectral analysis derived from $Y_{1}, Y_{2} \& Y_{3}$ bands showed that the combinations of the parameter M with $\mathrm{N}, \mathrm{K}$ or E parameters are the most effective. (2) The combinations of E with N and K are less effective than that with M , i e, the solute-solvent

hydrogen bonding has a neglectable role when combined with dielectric constant alone or with refractive index, while has a role when combined with refractive index only (M). The combinations without E is more effective than that with E . (3). The compounds gave visible band $\left(\mathrm{Y}_{4}\right)$ e g 2-\& 4-Cl, 2-CH3 and $2-\mathrm{OCH}_{3}$ compounds were affected strongly by the three parameters $(E, K \& N)$ separated or combined with each other. However, the M parameter alone gives poor correlation but if it is combined with the other parameters, the correlationbecomes good. So, the solute-solvent hydrogen bonding, refractive index and dielectric constant can explain the spectral shifts.

However, the data based on the three parameters equation give more explanation (give moderate to strong fit to the observed spectral shifts).(1) The dielectric constant or the refractive index when combined with solute-solvent hydrogen bonding and the solute permanent dipole-solvent induced dipole interaction, gave the same effects which are higher than the effects resulted from the combination of dielectric constant with solute-solvent hydrogen bonding and solute permanent di-pole-solvent permanent dipole interaction. (2) The compounds which gave $\mathrm{Y}_{4}$ (visible band) are the mostly affected by the solvent parameters based on one, two and three parameter equations. The four-parameters equation gives a best fit to the observed spectral shifts. The four combination is the more effective in the most compounds except for the compounds which gave $\mathrm{Y}_{4}$. However, for the $3-\mathrm{NO}_{2}$ compound based on $\mathrm{Y}_{1}$, the distribution of the solvent around the solute from the Frank-Condon principle points that the forces present are distributed in a manner to cancel each other. This explains the inapplicability of four parameters equation for the $3-\mathrm{NO}_{2}$. Also, the electron donor compounds are more effective than the electron withdrawing compounds by the four solvent parameters together based on $\pi-\pi^{*}$ transition ( $\mathrm{Y}_{1}$ ) and the visible bands $\left(\mathrm{Y}_{4}\right)$ and it reversed based on $n-\pi^{*}$ transition band ( $\mathrm{Y}_{2}$ ).
